About the journal

The International Scientific Periodical Journal "Modern Technology and Innovative Technologies" has been published since 2017 and has gained considerable recognition among domestic and foreign researchers and scholars.

Periodicity of publication: Quarterly

The journal activity is driven by the following objectives:

Broadcasting young researchers and scholars outcomes to wide scientific audience

Fostering knowledge exchange in scientific community

Promotion of the unification in scientific approach

Creation of basis for innovation and new scientific approaches as well as discoveries in unknown domains

The journal purposefully acquaints the reader with the original research of authors in various fields of science, the best examples of scientific journalism.

Publications of the journal are intended for a wide readership - all those who love science. The materials published in the journal reflect current problems and affect the interests of the entire public.

Each article in the journal includes general information in English. The journal is registered in INDEXCOPERNICUS.

Sections of the Journal:

Library of Congress Classification Outline	Sections
Subclass TJ / TJ1-1570	Mechanical engineering and machinery
Subclass TK / TK1-9971	Electrical engineering.
Subclass TA / TA165	Engineering instruments, meters, etc. Industrial instrumentation
Subclass TK / TK5101-6720	Telecommunication
Subclass TK / TK1-9971	Electrical engineering. Electronics. Nuclear engineering
Subclass TN / TN1-997	Mining engineering. Metallurgy
Subclass TS / TS1950-1982, TS2120-2159	Animal products., Cereals and grain. Milling industry
Subclass TS / TS1300-1865	Textile industries
Subclass TK / TK7800-8360	Electronics
Subclass T / T55.4-60.8	Industrial engineering. Management engineering
Subclass T / T351-385	Mechanical drawing. Engineering graphics
Subclass TA / TA1001-1280, Subclass TL / TL1-484, Subclass TE / TE1-450, Subclass TF / TF1-1620	Transportation engineering, Motor vehicles. Cycles, Highway engineering. Roads and pavements, Railroad engineering and operation
Subclass TH / TH1-9745	Building construction
Subclass T / T55-55.3	Industrial safety. Industrial accident prevention
Additional sections	<i>Innovative economics and management, Innovations in pedagogy, Innovative approaches in jurisprudence, Innovative philosophical views</i>

Requirements for articles

Articles should correspond to the thematic profile of the journal, meet international standards of scientific publications and be formalized in accordance with established rules. They should also be a presentation of the results of the original author's scientific research, be inscribed in the context of domestic and foreign research on this topic, reflect the author's ability to freely navigate in the existing bibliographic context on the problems involved and adequately apply the generally accepted methodology of setting and solving scientific problems.

All texts should be written in literary language, edited and conform to the scientific style of speech. Incorrect selection and unreliability of the facts, quotations, statistical and sociological data, names of own, geographical names and other information cited by the authors can cause the rejection of the submitted material (including at the registration stage).

All tables and figures in the article should be numbered, have headings and links in the text. If the data is borrowed from another source, a bibliographic reference should be given to it in the form of a note.

The title of the article, the full names of authors, educational institutions (except the main text language) should be presented in English.

Articles should be accompanied by an annotation and key words in the language of the main text and must be in English. The abstract should be made in the form of a short text that reveals the purpose and objectives of the work, its structure and main findings. The abstract is an independent analytical text and should give an adequate idea of the research conducted without the need to refer to the article. Abstract in English (Abstract) should be written in a competent academic language.

The presence of UDC, BBK

Acceptance of the material for consideration is not a guarantee of its publication. Registered articles are reviewed by the editorial staff and, when formally and in substance, the requirements of the journal are sent to peer review, including through an open discussion using the web resource www.sworld.education

Only previously unpublished materials can be posted in the journal.

Regulations on the ethics of publication of scientific data and its violations

The editors of the journal are aware of the fact that in the academic community there are quite widespread cases of violation of the ethics of the publication of scientific research. As the most notable and egregious, one can single out plagiarism, the posting of previously published materials, the misappropriation of the results of foreign scientific research, and falsification of data. We oppose such practices.

The editors are convinced that violations of copyrights and moral norms are not only ethically unacceptable, but also serve as a barrier to the development of scientific knowledge. Therefore, we believe that the fight against these phenomena should become the goal and the result of joint efforts of our authors, editors, reviewers, readers and the entire academic community. We encourage all stakeholders to cooperate and participate in the exchange of information in order to combat the violation of the ethics of publication of scientific research.

For its part, the editors are ready to make every effort to identify and suppress such unacceptable practices. We promise to take appropriate measures, as well as pay close attention to any information provided to us, which will indicate unethical behavior of one or another author.

Detection of ethical violations entails refusal to publish. If it is revealed that the article contains outright slander, violates the law or copyright rules, the editorial board considers itself obliged to remove it from the web resource and from the citation bases. Such extreme measures can be applied only with maximum openness and publicity.

Editorial board

- Averchenkov Vladimir Ivanovich, Doctor of Technical Sciences, Professor, Bryansk State Technical University, Russia
- Angelova Polya Georgieva, Doctor of Economic Sciences, Professor, Economic Academy D A Tsenova, Svishtov, Bulgaria, Bulgaria
- Animica Evgenij Georgievich, Doctor of Geographical Sciences, Professor, Ural State University of Economics, Russia
- Antonov Valerij Nikolaevich, Doctor of Technical Sciences, Professor, National Technical University of Ukraine "Kiev Polytechnic Institute", Ukraine
- Antrapeva Nadezhda Mihajlovna, Doctor of Chemical Sciences, Professor, National University of Life and Environmental Sciences of Ukraine, Ukraine
- Ahmadiyev Gabdulhat Malikovich, Doctor of Veterinary Sciences, Professor, Kazan (Volga) Federal University, Russia
- Bazheva Rima Chamalovna, Doctor of Chemical Sciences, Professor, Kabardino-Balkarian State University named after H M Berbekov, Russia
- Batyrgareeva Vladislava Stanislavovna, Doctor of Law, Research Institute for the Study of Crime Problems named after academician V V Stashisa NAPRN of Ukraine, Ukraine
- Bezdenzhnyh Tatyana Ivanovna, Doctor of Economic Sciences, Professor, St Petersburg State University of Economics, Russia
- Blatov Igor Anatolevich, Doctor of Physical and Mathematical Sciences, Professor, Volga State University of Telecommunications and Informatics, Russia
- Burda Aleksey Grigorevich, Doctor of Economic Sciences, Professor, Kuban State Agrarian University, Russia

Abstract. The article investigated properties cutting tool material of ultrapowders Al_2O_3 - 50 wt. % WC which have got hot pressing method and the study of their properties. To obtain cutting inserts based on aluminum oxide and tungsten monocarbide with high functional capabilities, the phase components of the initial powders are selected and their homogenized during mixing, hot pressing with the selection of optimal sintering modes with the direct passage of a high-ampere current through a graphite mold. The sintering regime has a great influence on the final properties of the ceramic material. The optimum sintering temperature of ceramics depends on the dispersion of the original powder, the presence of impurities, additives and the duration of heating. It was found that in order to reduce fragility and obtain tool ceramics with high reliability, it is sometimes necessary to exclude even the smallest porosity caused by the ingress of dust from the air.

Key words: composite material, tool ceramics, alumina, tungsten monocarbide, sintering temperature, hot pressing.

Introduction.

Numerous tool ceramics are based on aluminum oxide. Along with the advantages (high hardness, especially at elevated temperatures, chemical inertness and, accordingly, high wear resistance, unlimited raw materials), oxide ceramics has a number of disadvantages: high fragility, low resistance to thermal and mechanical shock. Despite this, materials based on aluminum oxide have found application as cutting tools for machining high-hardness metal alloys and other difficult-to-machine materials [1, 2].

The use of hot pressing in the preparation of oxide ceramics makes it possible to reduce the sintering temperature and obtain a material with a density close to the theoretical one. So from alumina of various grades without additives and with the addition of 0.2...0.4 % MgO at a pressure of 50 MPa and temperatures of 1,600...1,700 °C, samples with a density of 98.5...99.5 % can be obtained. Such density during conventional sintering is achieved only at a temperature of 1,800...1,900 °C [3, 4].

Sintering of alumina is a fairly radiated process. It occurs under the influence of the following mass transfer mechanisms: viscous flow, plastic deformation, evaporation-condensation, volumetric, grain-boundary and surface diffusion. In hot pressing, the main mechanisms of ceramic compaction at the final stage are plastic deformation and diffusion [5, 6].

The sintering regime has a great influence on the final properties of the ceramic. The optimum sintering temperature for ceramics depends on the dispersion of the initial powder, the presence of impurities, additives and the duration of heating. So, with a powder grain size of 0.5 ...1.0 μm, the oxide ceramic plates are sintered at 1,710 °C for 5...10 minutes. With an increase in temperature 1,780...1,820 °C, exposure can be reduced to 1...2 minutes. It has been established that short exposures at high temperatures are optimal [7, 8].

The work continues the research carried out by the authors in previous years, and is based on the results and scientific heritage, partially published in the works [9–12].

Main text.

The structure of tool ceramics has the following properties: high material density, strength of interphase and grain boundaries, high dispersion and uniformity of distribution of structural components, minimum size of defects that can serve as a source of destruction, absence of low-melting components that reduce high-temperature strength, high hardness and resistance to crack propagation. The mechanical characteristics of oxide ceramics are directly related to the average grain size in the material. The introduction of 15...30 % carbides (TiC, WC, Cr₂C₃, Mo₂C) into aluminum oxide makes it possible to increase the mechanical characteristics due to even greater refinement of the structure [13, 14]. Titanium carbide is the most commonly used tool in the industry.

The data of a comparative study of the kinetics of growth of alumina grains with MgO (0.6 %) and TiC (30 %) additives showed that the introduction of both additives reduces grain growth during hot pressing [15]. Ceramic material is characterized by covalent or ionic bonds; it is difficult to deform due to strong mutual bonds between atoms [16]. When a stress is applied above the ultimate strength, brittle fracture occurs in ceramics with almost no deformation. According to Griffiths theory, the fracture strength of brittle materials is expressed by the equation:

$$\sigma_f = \frac{K_{Ic}}{\sqrt{\pi \cdot C}}, \quad (1)$$

where K_{Ic} is the fracture toughness; C is the material damage value.

To reduce the brittleness of materials (that is, to increase their strength), it is necessary either to increase K_{Ic} , or to decrease C . In this case $K_{Ic} = \sqrt{2 \cdot E \cdot \gamma}$ (E is Young's modulus, γ is the destruction energy). Therefore, K_{Ic} can be increased by increasing Young's modulus, obtaining a sintered material with a fine texture close to the theoretical density, or by increasing γ , controlling the structure and firing conditions, increasing the uniformity of the structure.

To ensure the reliability of ceramic materials, it is necessary to reduce the scatter of product quality indicators [17, 18]. In particular, for ceramics used as an engineering material, the reliability is increased by reducing the spread of strength. This spread is also closely related to the presence of pores and cracks in the material. Therefore, in order to reduce fragility and obtain machine-building ceramics with high reliability, it is sometimes necessary to eliminate even the smallest porosity caused by the ingress of dust from the air, which was not paid attention to in the manufacture of ceramics by traditional methods. In the production of machine-building ceramics, even if using the same with traditional molding and sintering processes, on the basis of a strictly controlled production process, the formation of cracks and residual stresses arising from the formation of tiny pores due to the mixing of foreign bodies (plasticizing additives) during molding and shrinkage should be avoided during drying and firing. At the same time, the number of dislocations remaining in the fired products should be minimized, ensuring their more uniform distribution. From this point of view, the method of hot pressing by direct current transmission is of considerable interest, since molding proceeds without the use of any plasticizing additives and with a minimum temperature gradient over the section of the graphite mold.

The design of presses for hot pressing is determined by the method of heating and applying pressure, pressing temperatures, the need to use a protective gas environment or vacuum, and a number of other factors [19, 20].

For the manufacture of plates, powders of aluminum oxide Al_2O_3 with a dispersion of $0.06 \mu m$ and tungsten monocarbide with a dispersion of $0.07 \mu m$, obtained by the plasma-chemical method, were used. Micrographs of powders are shown in Fig. 1 and Fig. 2.

Fig. 1. Aluminum oxide nanopowder

Fig. 2. Tungsten monocarbide nanopowder

The density of the samples was determined by the method of hydrostatic weighing in water. Structural studies were carried out by scanning electron microscopy (JSM-840) on fractures of hot-pressed samples, thin sections, as well as initial powders.

To study the physical and mechanical properties, samples and thin sections were prepared from the central part of the sample. To measure *HRA*, a diamond pyramid was pressed in on a TM-12 hardness tester. The ultimate bending strength is determined by the three-point bending method on the MP-1-0.5 mechanism.

In cemented carbide technology, ISO sintered carbide grades for cutting tools, mining equipment and wear parts are listed in ascending / descending order of hardness / toughness. Toughness is generally determined by transverse fracture toughness and is commonly used to characterize sintered carbide alloys. In the industry, the terms "toughness" and "strength" are often used instead of one another as a measure of a material's resistance to mechanical shock. While shear fracture resistance determines the fracture resistance under three-point bending loading, toughness has been separated from this property because it is a measure of the energy absorbed before fracture.

The principles of fracture mechanics have been used to determine fracture toughness parameters such as K_{Ic} and G_{Ic} , which give an indication of the resistance of a material to fracture in the presence of a sharp notch.

Palmquist indentation cracking tests have been used to describe the toughness of sintered carbide alloys. These tests give a measure of the resistance to indentation cracking of a brittle material along the length of the cracks (L_c) arising from the indentation from the indenter under the applied load P . The total length of surface cracks originating from the indentation angles is:

$$L_c = \alpha \cdot P. \quad (2)$$

The Palmquist fracture toughness parameter of fracture toughness is:

$$W = \frac{1}{\alpha}, \quad (3)$$

where α is a constant (the slope of the graph of the dependence of L_c on P).

Such tests have a number of advantages over conventional shear fracture tests: firstly, there is no need for specially shaped specimens, and secondly, the number of prototypes required for such tests is much less than required for conventional three-point bending tests, and thirdly, during these tests, the hardness is automatically determined.

Tool life during cutting (in minutes) on IIX15 steel (HRC-58-60) was determined under the following conditions: cutting speed 400 m/min, feed 0.1 mm/rev, cutting depth 0.3 mm.

From the prepared powders, billets with a diameter of 20 mm and a weight of 9 g were pre-tableted. For hot pressing, an MIII-7 graphite with a maximum pressure of 50 MPa at temperatures above 1,200 °C was used as a mold. At this pressure, the temperature of the beginning and end of shrinkage was determined, which was determined by a displacement and acoustic emission sensor. The beginning of deformation is about 900 °C, and the end of shrinkage is 1,600...1,630 °C. Therefore, the temperature was limited to 1,650 °C. Table 1 presents data on the hot pressing process.

Table 1

Electrical parameters for sintering with direct current

<i>t</i> , min	U_1 , V	I_1 , A	U_2 , V	I_2 , A	$I_1 \cdot U_1$, kW	P , MPa	T , °C
1	160	19	3.5	870	3.04	10	180
2	160	29	3.5	1,320	4.64	10	360
3	160	36	3.4	1,690	5.76	10	1,070
4	160	39	3.4	1,830	6.24	10	1,470
5	160	40	3.3	1,940	6.4	50	1,600
6	130	27	2.5	1,404	3.51	50	1,600
10	–	–	–	–	–	50	1,200
20	–	–	–	–	–	50	700
30	–	–	–	–	–	10	300

Cutting plates with dimensions (11.75×11.75×4.75) mm were prepared from the samples and their resistance was determined when cutting hardened IIX15 steel according to the above modes. The best result is 29 minutes, which is 30 % more than for standard BOK-71 plates produced by the Svetlovodsk hard alloys plant (22 minutes).

When studying the structures of WOK-71 and the resulting ceramics, the grain sizes of the constituent phases of aluminum oxide and tungsten and titanium carbides are comparable (2...5 microns). However, the density of the obtained ceramics 50 % Al₂O₃-50 % WC – 5.96 g/cm³ is higher than that of BOK-71 – 4.2...4.27 g/cm³, which contributes to more efficient heat removal from the cutting zone and, thereby, lowering the temperature in it. Thus, the use of WC additives instead of TiC in the production of cutting inserts from aluminum oxide seems promising.

Further investigation of the structure and properties of the obtained oxide-carbide ceramics in Table 2 shows some of the physical and mechanical properties of the materials obtained. The microstructure of oxide-carbide ceramics is shown in Fig. 3.

Table 2

Physical and mechanical properties of the obtained materials

N_0	P , MPa	T , °C	ρ , g/cm ³	HRA	σ , MPa	K_{Ic} , mn · m ^{-3/2}	Durability T , min
1	40	1,550	5.68	93	530	3.5	22
2	50	1,600	5.96	94	590	5.8	29
3	50	1,650	5.83	93	560	5.2	25

Fig. 3. Microstructure of oxide-carbide ceramics with a composition 50 % Al₂O₃ – 50 % WC

When studying the structure and properties of the obtained oxide-carbide ceramics, the following conclusions can be drawn:

– the optimum sintering temperature of the mixture under a pressure of 1,600 °C (1,550 °C is insufficient for these holding times, and 1,650 °C exceeds the temperature of the WC-Al₂O₃ interfacial interaction, at which CO is released and closed porosity is formed);

– the pressing pressure is limited only by the characteristics of the MIF-7 graphite and is 50 MPa, and the maximum pressure is applied only when the maximum temperature in the compact is reached (for complete degassing of the sorbed gases). Applying maximum pressure at lower temperatures results in increased porosity due to the presence of sorbed gases;

– the grain size of the structural components of ceramics 2...5 microns is not optimal and was obtained not during sintering, but during preparation of the mixture for hot pressing (apparently dry mixing does not contribute to the destruction of Al₂O₃ and WC agglomerates and obtaining a homogeneous structure, in which it is possible to obtain submicron grains during sintering). Presumably wet mixing with surfactants is required.

Conclusion and findings.

The studies have shown that to obtain cutting Al₂O₃ – WC inserts with high functional capabilities, it is necessary to optimize the ratio of the phase components

of the initial powders and their homogenization during mixing, to perform molding by hot vacuum pressing under optimal conditions, to polish the cutting inserts to exclude microcrack nuclei, to optimize the parameters cutting various metals and alloys.

Аннотация. Статья посвящена получению инструментальной керамики с ультрадисперсных порошков Al_2O_3 - 50 мас. % WC методом горячего вакуумного прессования и исследованию их свойств. Для получения режущих пластин на основе оксида алюминия и монокарбида вольфрама с высокими функциональными возможностями проводится подбор фазовых составляющих исходных порошков и их гомогенизация в процессе смешивания, горячее прессование с подбором оптимальных режимов спекания при прямом пропускании высокоамперного тока через графитовую пресс-форму. Режим спекания оказывает большое влияние на конечные свойства керамики. Оптимальная температура спекания керамики зависит от дисперсности исходного порошка, наличия в нём примесей, добавок и продолжительности нагревания. Выявлено, что для снижения хрупкости и получения инструментальной керамики с высокой надёжностью бывает необходимо исключить даже мельчайшую пористость, вызываемую попаданием пыли из воздуха.

Ключевые слова: композиционный материал, инструментальная керамика, оксид алюминия, монокристалл вольфрама, температура спекания, горячее прессование.
